Working Principle

The electric motor drives the cylinder for rotation by reduction gears while wheel reducer with peripheral rack transmission or the low speed synchronous motor directly drives the cylinder to rotate by the peripheral rack wheel reducer transmission. The crushed ore and steel rod inside the cylinder can be thrown and rushed down to a certain height under the eccentric force and frictional force as a result of action of gravity. Crushed ores are discharged from cylinder through discharging part. The materials to be ground continuously go into the cylinder from the ore feeding mouth and crushed by the moving grinding media, and then discharged under the overflow and the force of continuous feeding to go to the next procedure.
